TITLE OF INVENTION

DEVICE FOR INVESTIGATING MATERIALS

APPLICANT(S) FOR DO/EO/US

Frank Rinn

Applicant herewith submits to the United States Designated/Elected Office (DO/EO/US) the following items and other information:

1. ☒ This is a **FIRST** submission of items concerning a filing under 35 U.S.C. 371.
2. ☐ This is a **SECOND** or **SUBSEQUENT** submission of items concerning a filing under 35 U.S.C. 371.
3. ☒ This is an express request to promptly begin national examination procedures (35 U.S.C. 371(f)).
4. ☐ The US has been elected by the expiration of 19 months from the priority date (PCT Article 31).
5. ☒ A copy of the International Application as filed (35 U.S.C. 371(c)(2))
 - a. ☐ is attached hereto (required only if not communicated by the International Bureau).
 - b. ☒ has been communicated by the International Bureau.
 - c. ☐ is not required, as the application was filed in the United States Receiving Office (RO/US).
6. ☒ A English language translation of the International Application as filed (35 U.S.C. 371(c)(2)).
7. ☐ Amendments to the claims of the International Application under PCT Article 19 (35 U.S.C. 371(c)(3))
 - a. ☐ are attached hereto (required only if not communicated by the International Bureau).
 - b. ☐ have been communicated by the International Bureau.
 - c. ☐ have not been made; however, the time limit for making such amendments has NOT expired.
 - d. ☐ have not been made and will not be made.
8. ☐ An English language translation of the amendments to the claims under PCT Article 19 (35 U.S.C. 371(c)(3)).
9. ☒ An oath or declaration of the inventor(s) (35 U.S.C. 371(c)(4)).
10. ☐ An English language translation of the annexes to the International Preliminary Examination Report under PCT Article 36 (35 U.S.C. 371(c)(5)).

Items 11. To 16. Below concern other document(s) or information included:

11. ☐ An Information Disclosure Statement under 37 C.F.R. 1.97 and 1.98
12. ☐ An assignment document for recording. A separate cover sheet in compliance with 37 CFR 3.28 and 3.31 is included.
13. ☒ A FIRST preliminary amendment.
☐ A SECOND or SUBSEQUENT preliminary amendment.
14. ☐ A substitute specification.
15. ☐ A change of power of attorney and/or address letter.
16. ☒ Other items or information: 2 sheets of drawings

In the Claims:

Cancel Claim 1, without prejudice.

Add the following new Claims 30-53:

30. (New) A device for examining materials comprising
a pulse generator for generating a pulse that can be
introduced into the material,
at least one sensor configured for being positioned with
respect to the material so as to detect the pulse, and
an electronic evaluation device for discriminating the
pulse from interfering pulses, with the electronic evaluation
device being positioned directly adjacent or integrated in
said one sensor.

31. (New) The device of Claim 30, wherein the pulse is
a mechanical and/or electrical pulse.

32. (New) The device of Claim 30 wherein the electronic
evaluation device includes means for generating an electrical
signal.

33. (New) The device of Claim 32 wherein the electrical
signal is connected for transmission to a central unit.

34. (New) The device of Claim 33 wherein the central

unit comprises a personal computer.

35. (New) The device of Claim 30, wherein said device comprises a plurality of said sensors, and wherein an electronic evaluation device is positioned directly adjacent or integrated in each sensor.

36. (New) The device of Claim 35 wherein said sensors are electrically interconnected.

37. (New) The device of Claim 35 wherein each of the sensors is operatively connected to a central unit.

38. (New) The device of Claim 35 wherein each of the sensors is operatively connected to a central unit via a transmitter-receiver unit associated with each sensor.

39. (New) The device of Claim 35 wherein each of the sensors has a vibration damper associated therewith.

40. (New) The device of Claim 39 wherein each vibration damper is a piezoelectric element.

41. (New) The device of Claim 35 wherein a transmission pin is associated with each sensor.

42. (New) The device of Claim 35 wherein a clock is associated with each sensor.

43. (New) The device of Claim 35 wherein an identification symbol is associated with each sensor.

44. (New) The device of Claim 35 wherein a storage for measurement results is associated with each sensor.

45. (New) The device of Claim 35 wherein a display for

REMARKS

This Second Preliminary Amendment is for the purpose of correcting a typographical error in the directions to cancel Claims 2-29 contained in the initial Preliminary Amendment filed with the application on November 9, 2001. This typographical error is evidenced by the statement in the Remarks of the Preliminary Amendment to eliminate claims which are multiple dependent and further by the original Transmittal indicating only one claim being submitted. Entry of this Amendment is requested prior to the calculation of the filing fee.

Respectfully submitted,

Charles B. Elderkin

DEVICE FOR INVESTIGATING MATERIALS

The invention relates to a device for examining materials, in particular trees, other kinds of wood, and concrete, with a pulse generator for generating a pulse that can be introduced into the material, with at least one sensor adapted for being associated to the material for detecting the pulse, and with an electronic evaluation device for discriminating the pulse from interfering pulses.

Devices for examining materials of the initially described kind are known from practice, and they exist in a large variety of types. They are, for example, devices, wherein the pulse time delay of shock waves is measured. From this pulse time delay, conclusions are drawn with respect to the quality of the material being examined. In the case of wood, for example, utility poles, the time delay of the shock waves correlates in the direction of growth or grain with the modulus of elasticity in the bending of wood, which enables an assessment of the load capacity, and the therefrom dependent categorization into quality classes. This influences the purchase price in the case of new poles.

In most cases, it is common to introduce into the material the shock wave or the pulse with a hammer serving as a pulse generator, either in a direct manner or via a screw or a bouncing pin. In the case of an axial irradiation of a pole by sound waves, the pulse is typically introduced at the front end. A sensor arranged at the other end of the material or pole detects the pulse that has been introduced into the material. A current pulse corresponding to this pulse is then guided from the sensor to a central electronic evaluation device, where the current pulse is analyzed by discriminating interfering pulses.

More specifically, an acceleration sensor in the pulse-generating hammer transmits in the instant of applying the stroke, the resultant current pulse via a line to a central electronic unit or electronic evaluation device, which analyzes the pulse, and starts a clock, depending on the result, namely a successful discrimination from, for example, interference vibrations. As soon as the sensor at the other end of the material or the other end of the measured length registers the arrival of the shock wave, it will likewise transmit a corresponding current pulse to the central electronic unit, which stops the clock, if the pulse meets the requirements with respect to intensity and length. Both the pulse from the hammer and the pulse from the sensor must each be electronically discriminated, i.e., be distinguished from other vibrations. This occurs each time in the central electronic evaluation device. For purposes of being able to distinguish between real pulses and spurious pulses, a user may normally adjust "gain" and "offset" in the central electronic evaluation device. From the time delay of the pulse and the distance between shock application and detector, it is possible to determine the pulse or shock velocity. Same allows to make statements as to the internal condition and the quality of the material being examined or the test piece, not only in the case of wood, but also in the case of concrete and other materials.

In the known device, the electronic signals of the acceleration sensors, the pulse generator, and the detectors, are transmitted via cables to a central electronic detection and evaluation device. This device also accommodates an accurate electronic clock. The discrimination and evaluation of the pulses, which were converted into electronic current pulses, previously

introduced, and subsequently detected, thus occurs in a central location by means of corresponding electronic circuits. In this connection, the pulse shape is decisive for differentiating between real pulses and interference pulses. Thus, the pulse shape should not be altered or falsified on its way from the sensor through the cable to the electronic evaluation device, for example, by electromagnetic interferences or technical cable properties. To accomplish this, the transmission cables must be shielded and be of an extremely high quality, which leads to high prices, limited length of few meters, and restricted handling. Cables of this kind with a corresponding shielding react very sensitively to low temperatures and other external effects, so that they can be used only with limitations, and are very prone to interference. For example, for purposes of avoiding interferences, such cables should not extend in a loop. In particular, in the case of very long or large test pieces of the material being examined, it is not possible to use the known device, since there exist no adequately long cables, which enable an interference-free transmission of current pulses from the sensor or sensors to the central electronic evaluation device.

Consequently, the use of the known device for examining materials, in particular with respect to large test pieces, is very restricted on the materials being tested. A universal application of the known device is therefore not possible.

It is therefore an object of the present invention to describe a device for examining materials of the initially described kind, which enables a universal application with constructionally simple means, in particular also in the case of large test pieces of the material being examined.

The foregoing object is accomplished by a device for

examining materials with the characterizing features of
claim 1. Accordingly, a device for examining materials
of the initially described kind is designed and
constructed such that an electronic evaluation device is
5 associated to each sensor.

According to the invention, it has first been
recognized that the foregoing object is accomplished in a
surprisingly simple manner alone because of a suitable
arrangement of the electronic evaluation device.

10 Furthermore, in accordance with the invention, a separate
electronic evaluation device is associated for this
purpose to each sensor. This association of respectively
one electronic evaluation device to each sensor permits
avoiding great cable lengths between the sensors and the
15 electronic evaluation device, in particular with the use
of a plurality of sensors. In comparison therewith, it
is not possible to avoid in the case of most sensors,
great cable lengths with the use of a central electronic
evaluation device for all sensors in use, which are often
20 arranged at great distances between one another.

The device of the present invention makes it now
possible to perform the discrimination of pulses quasi
directly on the sensors with minimal communication
lengths. Since an electronic evaluation device is
25 associated to each sensor, the spacings between the
sensors are no longer important. Therefore, it would
also be possible to arrange the sensors at a great
distance between one another, while yet enabling a
reliable discrimination of pulses.

30 Consequently, the device for examining materials
according to the invention realizes a device, which
permits a universal application with constructionally
simple means, in particular also in the case of large
test pieces of the material being examined.

35 As regards the kind of pulse, two alternatives

present themselves. In this connection, the pulse could be a mechanical and/or an electrical pulse. A mechanical pulse is, for example, a shock wave, which is triggered, for example, by means of a hammer. However, it is also possible to introduce electrical pulses into the material being examined. In this instance, it is also possible to measure the time delay of the current pulse and/or its attenuation. The pulse may be a direct current or an alternating current pulse. In the case of the alternating current pulse, it is also possible to examine its frequency response while passing through the material.

As regards a very short and reliable communication length between the sensor and the electronic evaluation device, the latter could be arranged directly adjacent to the sensor or be integrated in the sensor. In particular, the integrated arrangement of the electronic evaluation device in the sensor ensures a particularly compact and evaluation-reliable configuration of the device.

As regards a particularly simple processing of the measured data generated by the device, the electronic evaluation device could include a device for generating an electronic signal. In this instance, the electronic evaluation device could be designed such that the electronic signal is generated exactly at the moment, when a real measurement pulse is detected, which is discriminated from interference pulses. In the simplest case, the signal could be an electronic, preferably digital standard pulse. In this case, one has in mind in particular a TTL pulse.

It would be possible to transmit an electronic signal, which is generated by the electronic evaluation device, to a central unit, which preferably is, for example, a portable computer. In such a central unit, it

would be possible to process the measured data in the form of, for example, time delays of the shock waves from the pulse input location to the respective sensor.

In particular with respect to a reliable
5 transmission of the signal from the sensors or the electronic evaluation device to the central unit, it would be possible to interlink the sensors and/or electronic evaluation device electrically. For an electrical connection, one could use standard cables of
10 the simplest kind, since it is not necessary to suppress here interferences or signal distortions. What matters is only a reliable transmission of an electronic standard signal. A costly discrimination in the central unit is no longer needed, since the decisive discrimination of
15 real pulses from interference pulses already occurs in the electronic evaluation device. It would be possible to provide a closed-loop line or a star-shaped line. In this instance, it is necessary to accommodate the respective case of application. This means that in the
20 case of large test pieces, a closed-loop line could be advantageous because of its shorter overall cable length as a whole.

As an alternative to a transmission via electrical lines, the transmission could occur by means of radio
25 waves, ultrasonic waves, or infrared radiation. To this end, it would be possible to associate to each sensor a transmitter-receiver unit for radio waves, ultrasonic waves, or infrared radiation. Via such a transmitter-receiver unit, it would be possible to transmit
30 especially the electronic signal of the electronic evaluation device, thereby avoiding extensive cabling.

In a concrete arrangement, one could associate a vibration detector to each sensor. The oscillation
35 detector is used for detecting mechanical pulses. In a particularly simple manner, the oscillation detector

could be a piezoelectric element.

For a reliable transmission of a mechanical and/or an electrical pulse from the test piece to the sensor, a transmission pin for the pulse could be associated to each sensor. In a constructionally very simple manner, the transmission pin could be a metal pin, preferably a steel pin. At the beginning of a measurement, such a transmission pin could be inserted into the test piece of the material being examined, whereupon the sensor is coupled with the transmission pin. In a particularly simple manner, the sensor could engage the transmission pin or suspend therefrom. If the material being examined consists, for example, of concrete, one could do without a transmission pin.

In the device for examining materials according to the invention, one measures, for example, the time delay of a pulse from a pulse input location to each individual sensor. In so doing, it is necessary to initialize the sensors. To this end, a clock could be associated to each sensor. For example, an initialization could occur in such a manner that the first sensor, which detects a real pulse, starts its clock and, in so doing, transmits at the same time a preferably electronic communication signal to the other sensors to reset their clocks to zero and to start them likewise. This initialization principle will be especially favorable, when the pulse is input or introduced in the direct vicinity of the first sensor.

Once a real pulse is detected, the electronic evaluation device transmits, for example, an electronic signal to a central unit. In this case, it is advantageous to associate to each sensor an individual identification means, so as to enable an allocation of the signals arriving at the central unit to the respectively transmitting sensor. To this end, the

sensors could identify themselves by a clear code.

In a further advantageous manner, it would be possible to associate to each sensor a storage for measurement results, which enables a direct readout of the measurement results on each sensor.

Furthermore, it would be possible to associate to each sensor a display for the measurement results, which permits reading the measurement results directly on the sensor.

A particularly advantageous development of the device for examining materials could be provided with at least three sensors. This would permit generating last but not least three-dimensional graphs of the results with respect to the internal condition of the test piece. The more sensors are used, the more detailed will be such a graph. In this instance, it is essential that the sensors can be associated to the material in a geometrically independent relationship from one another. A rigid arrangement of the sensors, for example, in a closed-loop form is not necessary. For an effective evaluation of the three-dimensional measurement data, it is only necessary that the geometric positions of the sensors be determined.

With respect to a particularly elegant and practical introduction of pulses, the sensor or a plurality of sensors could be realized as pulse generators. To this end, it would be possible to associate to at least one sensor a device for introducing pulses. Such a device could be formed, for example, by a piezoelectric element, which serves at the same time as a vibration detector. As an alternative or in addition thereto, the device for introducing pulses could be a pin, preferably a metal pin. Such a pin could connect to the sensor via a coupling piece of rubber. For introducing pulses, the pin could be activated by means of a pulse generator in

the form of a hammer.

As regards a reliable measurement of the pulses that are introduced by the pulse generator, it is essential that the introduced pulses be distinguished or

5 discriminated from interference pulses. Interference pulses may be generated, for example, during the examination of a tree by automobiles passing by in a neighboring street. Even people walking by the test piece being examined may generate interference pulses
10 above the ground or introduce them into the test piece. It will therefore be especially advantageous, when the sensors or electronic evaluation devices are able to recognize such interference pulses in each application individually already before the actual measurement. To
15 this end, the electronic evaluation device could include means for self-calibration. In this case, the detection threshold of the electronic evaluation device itself is adjusted to a level, which is above the level of all previously detected interference pulses or interference
20 vibrations. This self-calibration step could occur continuously, with a self-calibration being absent during the time of the actual measurement. With that, it is possible to suppress a substantial number of interference pulses right from the beginning.

25 As regards a simple determination of the positions of the sensors relative to one another, it would be possible to associate to the sensor or sensors pull-out measuring sticks. In the alternative, it would be possible to associate to the sensor or sensors a rope
30 with an angle display. The rope interconnects adjacent sensors. As a result, it would be possible to determine the distance and angle from an adjacent sensor. With a known sensor size, it is possible to approximate from the sensor distances and angles of the rope connection, the
35 geometry of the cross section of a sample in the tested

region, for example, the cross section of a tree.

As an alternative or in addition thereto, it would be possible to provide an infrared or laser distance measuring instrument. In connection with the central
5 unit, this would permit determining the position of the sensors and pulse input locations and displaying them as a three-dimensional image. In this case, it is possible to compute, display, and output a three-dimensional image of the internal condition directly from the determined
10 pulse data.

For a better understanding of the teaching according to the invention, the essential aspects of the teaching according to the invention are explained one more time in the following:

15 To generate within the scope of the device according to the invention, three-dimensional graphs of a condition, at least three sensors, preferably of the same type are arranged in a desired geometry around the cross section or test piece being examined. In the case of
20 standing trees, for example four to six sensors per cross section or stem section will suffice in most cases. The introduction of pulses may occur by means of a commercially available hammer. From the respective location of the pulse input, which occurs in different
25 places, a corresponding measured value is obtained, which results after a corresponding processing of the measured value, in a three-dimensional, quasi tomographic cross sectional image. The pulse input may occur in any desired places of the test piece.

30 In a concrete realization, each sensor comprises its own, independent electronic control or electronic evaluation device, which includes, if need be, an electronic timer or a clock. After their conversion into current pulses, for example, via piezoelectric crystals,
35 the mechanical or electrical pulses arriving from the

test piece of the material being examined, are electronically processed and discriminated directly in the sensor. External interfering influences are thus directly suppressed in the sensor. With that,
5 interferences, which have so far been problematic in the transmission system -- cables -- are precluded. Once a pulse arriving from the test piece is detected as correct, an electronic, preferably digital standard pulse, for example, TTL pulse will be generated. This
10 pulse can be transmitted via simple, cost-favorable standard cables of an almost unrestricted length, or even via radio, infrared, or ultrasound, to other sensors or to a central unit. In this process, the sensors identify themselves by a clear code.

15 Optionally, the sensors are able to detect not only arriving pulses, but also generate and input themselves pulses, for example, via the reversed piezoelectric effect, inasmuch as, in principle, the same technology is therefor required.

20 For example, it is possible to interlink the sensors in the form of a closed-loop line. However, the data may also be transmitted in a star-shaped configuration, or via radio, to a central unit with a display, storage, and output, or directly to a preferably portable computer.

25 In this arrangement, the number of sensors is quasi random. In an advantageous manner, each of these sensors identifies itself during the communication. It is necessary to identify the sensors only clearly and to allocate them in their position, to the position of the
30 pulse input being registered during each pulse input.

35 In the case of trees, it may become necessary to arrange the sensors at a height of several meters. This may occur by means of telescopic rods, since the sensors may be either driven in directly or arranged on driven-in pins.

A typical measuring sequence or process could be performed as follows. First, one determines on the test piece the correct position of the sensors. Subsequently, for example, for examining trees or wood, the sensors are mounted, screwed, flanged, preferably to pins that are driven or screwed into the wood, so as to ensure an adequately stable connection with the wood. Furthermore, one determines, if necessary, the three-dimensional geometry of the test piece, which may occur in a laser- and PC-assisted manner. Along with the determination of the geometry, the position of the sensors is determined. At the beginning of the measurement, all sensors are in a so-called "standby" position.

Depending on the task being posed, the introduction or input of pulses may occur in one location or in a plurality of locations of the test piece. Between the pulse input location and each sensor, this results in a measuring length with at least one individual measured value (for example, time delay, conductivity, damping). Consequently, each pulse input results in a list of measured values for each sensor. These values are allocated to the respective length between the pulse input location and sensor.

In a simple embodiment, a bouncing pin that is secured, for example, with rubber, hangs above each sensor. Via this pin, it is possible to introduce shock waves, preferably with the use of a commercially available hammer.

In a second operation after positioning the sensors, at least one stroke is applied to the mounted pulse input pins. The advantage of this procedure lies in that the coordinates of the pulse input are each given by the coordinates of the sensors that are determined in any case.

However, the pulse input may also occur in any other

locations, for example by means of a hammer and/or
bouncing pin. For a direct assessment of internal wood
damage, this procedure will already suffice, since the
examining expert is able to determine and allocate the
5 results directly. However, if it is intended to
determine and display as much as possible a complete
tomographic image, it will also be necessary to determine
the respective position of the pulse input in a
correspondingly exact manner.

10 The sensors are initialized either by the pulse
input -- via a cable connection between the hammer and
sensors -- or by a first sensor, which has identified an
arriving pulse. Initialized sensors start their internal
clocks and determine, for example the time frequency
15 until they receive the next pulse. The transmission of
the electronic standard pulses via cables or radio occurs
almost at light speed, and thus is by an order of
magnitude faster than the transmission of shock waves.
As a result, the time delay by the electronic
20 transmission of the initialization has no significant
effect on the measuring accuracy.

Each sensor transmits the time between
initialization and pulse detection to the other sensors
and/or to the central unit, where the values are
25 collected.

The results of the respective time delays are
printed preferably directly on paper or shown on any
portable, for example, watertight display.

The evaluation may be assisted by a computer, in
30 that the display is connected to such a computer, or that
direct use is made of a portable personal computer. The
point of the shock wave input and sensor positions are
entered either manually or graphically, or they
automatically result from the fact that the sensor, next
35 to which a stroke was applied, signals a zero time delay.

From the time delays of the respective connection segments between pulse input and sensor, quasi tomographic cross sectional images of the condition of the test piece result automatically. The number of connection segments and thus of the results is obtained as a function of the number n of the sensors, as follows:

If the pulse input does not directly occur on one of the sensors, n time delay results will be obtained per pulse, whereas $n-1$ results will be obtained, if the pulse is input directly on a sensor.

If the pulse is input on each sensor, $n(n-1)$ results will be obtained. In the case of only six sensors, and thus six shock input points on one tree, thirty measuring segments are obtained with corresponding information about the delay time, which results in a quasi tomographic cross sectional image. Since only few seconds are needed per pulse input, it is possible to determine in this way in a very short time a comprehensive information about the internal condition.

For example, when two sensor rings are arranged at different heights on a standing tree, for example, at foot level and head level, one will automatically obtain comprehensive data about the condition of the entire volume between these two rings. From two rings with six sensors each, 12 pulse inputs -- one each next to the sensor -- result in a total of 132 connection segments with corresponding time delay information. From this, it is possible to compose a relatively accurate image of the condition of the wood.

The device of the present invention is not limited to a certain arrangement of the sensors -- for example, around a cross section. Rather, it is possible to position the sensors freely. Likewise, since the number of sensors is not limited, it is thus also possible to determine the accuracy of the three-dimensional coverage

of the test piece, since the accuracy is defined by the number and position of the sensors as well as the number of pulse inputs. An EDP- assisted coverage of the position of the sensors and pulse input, as well as a
5 correspondingly automated evaluation enable an easy processing of the number of resulting values, which rapidly increases with the number of sensors. In this process it is necessary to determine or input only the geometry of the sample and the arrangement of the
10 sensors.

The geometry or surface topology of the test piece and the position of the sensors are the basis of further evaluations. The accuracy of their coverage defines the accuracy and expressiveness of the results. This coverage
15 may be sketchy or occur by means of commercially available distance measuring instruments. Likewise useful are laser distance measuring devices and position recording devices.

The device of the invention permits measuring the chronological and spatial intensity distribution of the pulses. In this connection, it is possible to input not
20 only individual pulses and record their arrival, but also pulse sequences of identical or fluctuating intensity and frequency.

The electronic evaluation device comprises means for discriminating the pulse from interference pulses. In this connection, it would here be possible to integrate a
25 corresponding software.

In a particularly advantageous manner, the device is
30 made waterproof for outdoor use, thereby ensuring a long and troublefree operation of the device.

It would be possible to place the sensor not only on a pin, but also on a star-shaped pin combination, which includes pin tips pointing in different directions. When
35 the arriving pulses are separately detected, each by the

individual tip, it will be possible to determine results over the spatial direction of the pulses, which is very interesting in the case of trees, since there are different radial and tangential propagation responses.

5 The bouncing pin, which can be actuated either by a hammer or a sensor, may be oriented in a different direction. This permits taking into account a different propagation response in the material.

10 In the device of the present invention, a plurality of sensors enable quasi tomographic determinations of the internal condition with only few measurements. In this instance, identically adjusted sensors of only one kind are needed, which reduces the costs of manufacturing. The sensors evaluate pulses from the material being
15 examined directly, independently, and thus "in situ", which reduces sources of interference and expense. For example, the shock input may occur by means of a commercially available hammer, which is very flexible and cost-favorable. The sensor connection requires only
20 simple, commercially available, and cost-favorable connection cables, or it may occur via radio or other methods of remote transmission, since only electronic standard pulses are transmitted, which are insensitive to external interferences.

25 Based on the technical characteristics of the system, it is possible to position on the test piece, without limitation, any desired number of sensors. As a result of using a sensor shielding, standard cables, and transmitted pulses, the device is extremely insensitive
30 to electromagnetic interference radiations, incorrect handling, mechanical loads, and other disturbances.

 Quasi tomographic cross sectional images result in an automatic and a very simple way.

35 Volume-relevant results are obtained with the use of as few as three sensors. A plurality of sensors permits

in a simple manner a three-dimensional coverage of the condition of almost any desired kind. A measurement can occur very rapidly by first inserting the pins, then mounting the sensors, and subsequently generating pulses by a shock or in any other fashion. Finally, the measurement results are noted or recorded. Only few minutes are needed for the therefor required two loops around the tree.

There exist various possibilities of improving and further developing the teaching of the present invention in an advantageous manner. To this end, reference may be made on the one hand to the dependent claims, and on the other hand to the following description of an embodiment of the device according to the invention with reference to the drawing. In conjunction with the description of the preferred embodiment of the device according to the invention with reference to the drawings, also generally preferred improvements and further developments of the teaching are described. In the drawings:

Figure 1 is a schematic view of an embodiment of the device according to the invention for examining materials in a state arranged on a tree; and

Figure 2 is a schematic top view of a sensor of the embodiment of Figure 1.

Figure 1 is a schematic view of the embodiment of the device according to the invention for examining materials. The device comprises a pulse generator 1 for generating a pulse that can be introduced into a material 2. A tree is used as the material 2 being examined.

Furthermore, the device includes six sensors 3 associated to the material 2 for detecting the pulse with six electronic evaluation devices 4 for discriminating the pulse from interference pulses. As regards a universal application of the device to even large test pieces, a separate electronic evaluation device 4 is associated to

each sensor 3.

The electronic evaluation device 4 performs the discrimination of real introduced pulses from interference pulses. No long communication paths are needed between the sensor 3 or a vibration detector and the electronic evaluation device 4. In the illustrated embodiment, the electronic evaluation device 4 is integrated in the sensor 3. The sensors 3 are connected to the material 2 by means of a transmission pin 5. In this connection, the sensors 3 engage the transmission pin 5 or suspend therefrom. By way of example, a device for introducing pulses is associated to one of the sensors 3 in the form of a pin 6. The pulses are introduced by a stroke with the hammer on pin 6.

The sensors 3 are interlinked via connection cables 7. Furthermore, a connection is provided between the sensors 3 and a central unit 8. The central unit 8 receives electronic signals, which are generated by the electronic evaluation devices 4 of the respective sensors 3, when a real pulse is detected. In this process, an individual code is determined for each sensor 3, so that the central unit 8 is able to allocate the arrival location of the detected pulse.

Figure 2 is a schematic top view of a sensor 3 of the embodiment of Figure 1. The sensor 3 includes an integrated electronic evaluation device 4. The pin 5 serving to connect to the material is coupled with the sensor 3 via a coupling piece 9. In direct connection with the coupling piece 9, a vibration detector 10 is provided, which is formed by a piezoelectric element. The electronic evaluation device 4 and the vibration detector 10 are coupled via an electric connection 11.

Both the transmission pin 5 and the coupling piece 9 may be made of a conductive material, preferably metal.

This ensures not only a transmission of vibrations from the material 2 to the vibration detector 10, but also a transmission of electrical pulses to the vibration detector 10 and, thus, via the electrical connection 11, to the electronic evaluation device 4. With that, it is possible to detect with the sensor 3 not only mechanical, but also electrical pulses.

The transmission of an electronic signal, which is generated by a special device associated to the electronic evaluation device 4, or of other signals from the sensor 3 may occur as an alternative to the transmission via cables 7, via a transmitter-receiver unit 12 for radio waves, ultrasonic waves, or infrared radiation. The transmitter-receiver unit also permits an initialization of the sensors 3 at the beginning of a measurement. In this case, the connection cables 7 may be omitted. The transmitter-receiver unit 12 may be used for transmitting all kinds of signals, measurement results, or the like.

The electronic evaluation device is used as an independent unit with a central processing unit.

As regards further advantageous developments of the device according to the invention for examining materials, the general part of the description as well as the attached claims are herewith incorporated by reference for purposes of avoiding repetitions.

Finally, it should be expressly pointed out that the above-described embodiment of the device according to the invention merely serves to describe in greater detail the claimed teaching, but without limiting it to this embodiment.

CLAIMS

1. Device for examining materials, in particular
5 trees, other kinds of wood, and concrete, with a pulse
generator (1) for generating a pulse that can be
introduced into the material (2), with at least one
sensor (3) adapted for being associated to the material
10 (2) for detecting the pulse, and with an electronic
evaluation device (4) for discriminating the pulse from
interference pulses,
characterized in that an electronic evaluation device is
associated to each sensor (3).

15 2. Device of claim 1, characterized in that the
pulse is a mechanical and/or electrical pulse.

3. Device of claim 1 or 2, characterized in that
electronic evaluation device (4) is arranged directly
20 adjacent to the sensor (3) or integrated in the sensor
(3).

4. Device of one of claims 1-3, characterized in
that the electronic evaluation device (4) is a device for
25 generating an electronic signal.

5. Device of claim 4, characterized in that the
signal is an electronic, preferably digital standard
pulse.

30 6. Device of claim 4 or 5, characterized in that
the signal is transmissible to a central unit (8).

7. Device of claim 6, characterized in that the
35 central unit (8) is a personal computer.

8. Device of one of claims 1-7, characterized in that the sensors (3) are electrically interlinked.

5 9. Device of claim 8, characterized in that the connection is realized by a closed-loop line or a star-shaped line.

10 10. Device of one of claims 6-9, characterized in that the transmission can be performed by means of a cable connection, radio waves, ultrasonic waves, or infrared radiation.

15 11. Device of one of claims 1-10, characterized in that a transmitter-receiver unit (12) for radio waves, ultrasonic waves, or infrared radiation is associated to each sensor.

20 12. Device of one of claims 1-11, characterized in that a vibration detector (10) is associated to each sensor (3).

25 13. Device of claim 12, characterized in that the vibration detector (10) is a piezoelectric element.

14. Device of one of claims 1-13, characterized in that a transmission pin (5) for the pulse is associated to each sensor (3).

30 15. Device of claim 14, characterized in that the transmission pin (5) is a metal pin, preferably steel pin.

35 16. Device of one of claims 1-15, characterized in that a clock is associated to each sensor (3).

17. Device of one of claims 1-16, characterized in that an identification means is associated to each sensor (3).

5

18. Device of one of claims 1-17, characterized in that a storage for measurement results is associated to each sensor (3).

10 19. Device of one of claims 1-18, characterized in that a display for the measurement results is associated to each sensor (3).

15 20. Device of one of claims 1-19, characterized in that at least three sensors (3) are provided.

20 21. Device of one of claims 1-20, characterized in that the sensors (3) are adapted for being associated to the material (2) in a geometrically independent relationship with one another.

25 22. Device of one of claims 1-21, characterized in that the sensor (3) or a plurality of sensors (3) is or are realized as pulse generators (1).

23. Device of one of claims 1-22, characterized in that a device for introducing pulses is associated to at least one sensor (3).

30 24. Device of claim 23, characterized in that the device for introducing pulses is a pin (6), preferably a metal pin.

35 25. Device of one of claims 1-24, characterized in that the pulse generator (1) is a hammer.

26. Device of one of claims 1-25, characterized in that the electronic evaluation device (4) includes means for self-calibration.

5

27. Device of one of claims 1-26, characterized in that pull-out measurement sticks are associated to the sensor or sensors (3).

10

28. Device of one of claims 1-27, characterized in that a rope with an angle display is associated to the sensor or sensors (3),

15

29. Device of one of claims 1-28, characterized in that an infrared or laser distance measuring instrument is provided.
